

# Files and I/O

# Introduction

- The java.io package, which provides support for I/O operations.
- A stream can be defined as a sequence of data.
- The InputStream is used to read data from a source.
- The OutputStream is used for writing data to a destination.
- The File class have several methods for working with directories and files such as creating new directories or files, deleting and renaming directories or files, listing the contents of a directory etc.

# Introduction

In Java, streams are the sequence of data that are read from the source and written to the destination.

An input stream is used to read data from the source. And, an output stream is used to write data to the destination.

```
class HelloWorld {  
    public static void main(String[] args) {  
        System.out.println("Hello, World!");  
    }  
}
```

# Introduction

For example, in our first Hello World example, we have used `System.out` to print a string. Here, the `System.out` is a type of output stream.

Similarly, there are input streams to take input.

Reading data from source

Writing data to destination

# Introduction

## Types of Streams

Depending upon the data a stream holds, it can be classified two types:

- Byte Stream

- Character Stream

# Introduction

## 1. Byte Stream

We use Byte Stream to read and write a single byte (8 bits) of data.

All byte stream classes are derived from base abstract classes called `InputStream` and `OutputStream`.

# Introduction

## 2. Character Stream

We use Character Stream to read and write a single character of data.

All the character stream classes are derived from base abstract classes Reader and Writer.

# Java InputStream Class

The InputStream class of the java.io package is an abstract superclass that represents an input stream of bytes.

Since InputStream is an abstract class, it is not useful by itself. However, its subclasses can be used to read data.

## Subclasses of InputStream

In order to use the functionality of InputStream, we can use its subclasses. Some of them are:

- FileInputStream

- ByteArrayInputStream

- ObjectInputStream

# Java OutputStream Class

The OutputStream class of the java.io package is an abstract superclass that represents an output stream of bytes.

Since OutputStream is an abstract class, it is not useful by itself. However, its subclasses can be used to write data.

## Subclasses of OutputStream

In order to use the functionality of OutputStream, we can use its subclasses. Some of them are:

- FileOutputStream

- ByteArrayOutputStream

- ObjectOutputStream

# Java FileInputStream Class

- The FileInputStream class of the java.io package can be used to read data (in bytes) from files.
- It extends the InputStream abstract class.

# Java FileInputStream Class

Method	Description
<code>int available()</code>	It is used to return the estimated number of bytes that can be read from the input stream.
<code>int read()</code>	It is used to read the byte of data from the input stream.
<code>int read(byte[] b)</code>	It is used to read up to <b>b.length</b> bytes of data from the input stream.
<code>int read(byte[] b, int off, int len)</code>	It is used to read up to <b>len</b> bytes of data from the input stream.
<code>long skip(long x)</code>	It is used to skip over and discards x bytes of data from the input stream.

```
import java.io.FileInputStream;

public class DataStreamExample {

    public static void main(String args[]){

        try{

            FileInputStream fin=new FileInputStream("D:\\VJV DDU\\2021-22\\MCA 2\\Lab\\files\\testout.txt");

            int i=0;

            while((i=fin.read())!=-1){

                System.out.print((char)i);

            }

            fin.close();

        }catch(Exception e){System.out.println(e);}

    }

}
```

# Java FileOutputStream Class

- The FileOutputStream class of the java.io package can be used to write data (in bytes) to the files.
- It extends the OutputStream abstract class.

# Java FileOutputStream Class

Method	Description
<code>protected void finalize()</code>	It is used to clean up the connection with the file output stream.
<code>void write(byte[] ary)</code>	It is used to write <b>ary.length</b> bytes from the byte <b>array</b> to the file output stream.
<code>void write(byte[] ary, int off, int len)</code>	It is used to write <b>len</b> bytes from the byte array starting at offset <b>off</b> to the file output stream.
<code>void write(int b)</code>	It is used to write the specified byte to the file output stream.

```
import java.io.FileOutputStream;

public class FileOutputStreamExample {

    public static void main(String args[]){

        try{

            FileOutputStream fout=new FileOutputStream("D:\\VJV DDU\\2021-22\\MCA 2\\Lab\\files\\testout.txt");
            String s="Welcome to DDU-MCA.";
            byte b[]=s.getBytes();//converting string into byte array
            fout.write(b);
            fout.close();

            System.out.println("success...");
        }catch(Exception e){System.out.println(e);}

    }

}
```

# Java ByteArrayInputStream Class

- The ByteArrayInputStream class of the java.io package can be used to read an array of input data (in bytes).
- It extends the InputStream abstract class.
- Note: In ByteArrayInputStream, the input stream is created using the array of bytes. It includes an internal array to store data of that particular byte array.

Methods	Description
<code>int available()</code>	It is used to return the number of remaining bytes that can be read from the input stream.
<code>int read()</code>	It is used to read the next byte of data from the input stream.
<code>int read(byte[] ary, int off, int len)</code>	It is used to read up to len bytes of data from an array of bytes in the input stream.

```
import java.io.*;
public class ReadExample {
    public static void main(String[] args) throws IOException {
        byte[] buf = { 35, 36, 37, 38 };
        // Create the new byte array input stream
        ByteArrayInputStream byt = new ByteArrayInputStream(buf);
        int k = 0;
        while ((k = byt.read()) != -1) {
            //Conversion of a byte into character
            char ch = (char) k;
            System.out.println("ASCII value of Character is:" + k + "; Special character is: " + ch);
        }
    }
}
```

# Java ByteArrayOutputStream

- The ByteArrayOutputStream class of the java.io package can be used to write an array of output data (in bytes).
- It extends the OutputStream abstract class.

# Java ByteArrayOutputStream

## Java ByteArrayOutputStream Class

Java ByteArrayOutputStream class is used to write common data into multiple files. In this stream, the data is written into a byte array which can be written to multiple streams later.

The ByteArrayOutputStream holds a copy of data and forwards it to multiple streams.

The buffer of ByteArrayOutputStream automatically grows according to data.

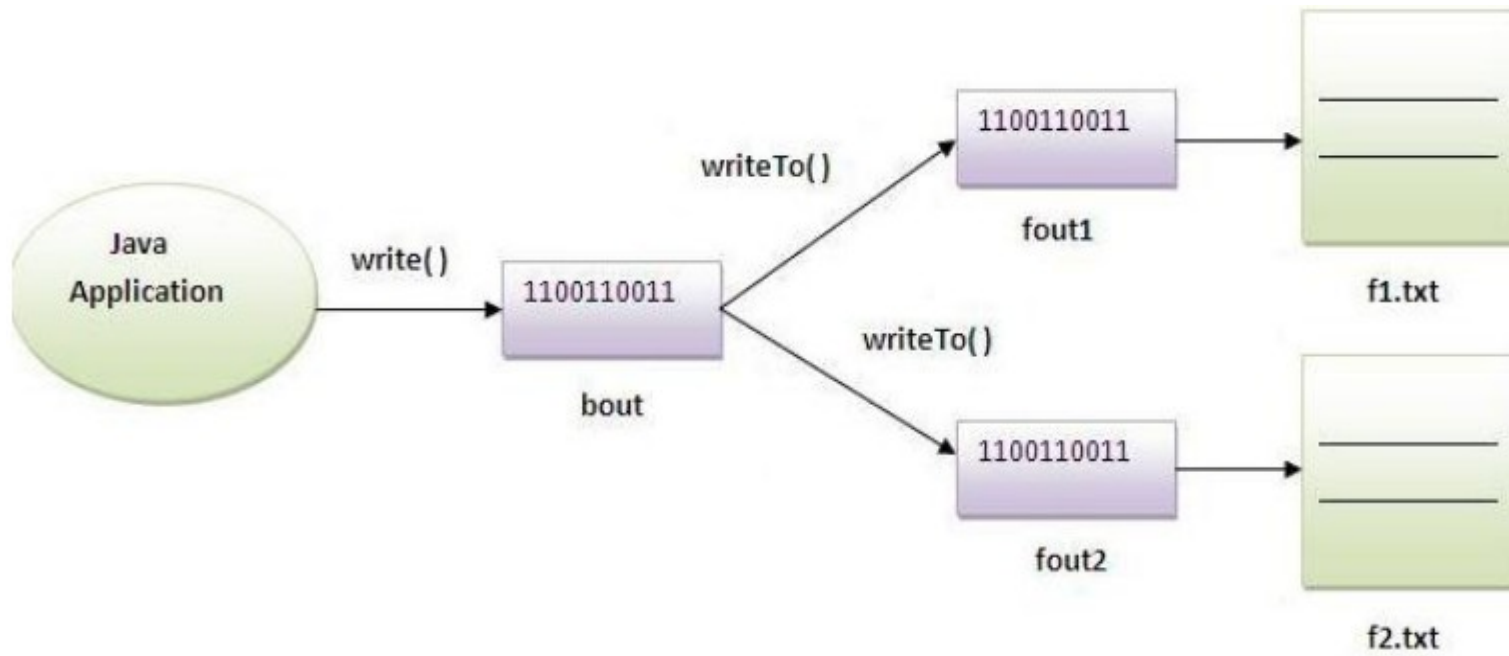

# Introduction

Method	Description
<code>int size()</code>	It is used to returns the current size of a buffer.
<code>byte[] toByteArray()</code>	It is used to create a newly allocated byte array.
<code>String toString()</code>	It is used for converting the content into a <code>string</code> decoding bytes using a platform default character set.
<code>String toString(String charsetName)</code>	It is used for converting the content into a string decoding bytes using a specified charsetName.
<code>void write(int b)</code>	It is used for writing the byte specified to the byte array output stream.

```
import java.io.*;
public class DataStreamExample1 {
public static void main(String args[]) throws Exception{
    FileOutputStream fout1=new FileOutputStream("D:\\VJV DDU\\2021-22\\MCA 2\\Lab\\files\\f1.txt");
    FileOutputStream fout2=new FileOutputStream("D:\\VJV DDU\\2021-22\\MCA 2\\Lab\\files\\f2.txt");

    ByteArrayOutputStream bout=new ByteArrayOutputStream();
    bout.write(65);
    bout.writeTo(fout1);
    bout.writeTo(fout2);

    bout.flush();
    bout.close();//has no effect
    System.out.println("Success...");
}
}
```

# Java ObjectInputStream

- The ObjectInputStream class of the java.io package can be used to read objects that were previously written by ObjectOutputStream.
- It extends the InputStream abstract class.

# Java ObjectInputStream

- Working of ObjectInputStream
- The ObjectInputStream is mainly used to read data written by the ObjectOutputStream.
- Basically, the ObjectOutputStream converts Java objects into corresponding streams. This is known as serialization. Those converted streams can be stored in files or transferred through networks.

# Java ObjectInputStream

- Now, if we need to read those objects, we will use the ObjectInputStream that will convert the streams back to corresponding objects. This is known as deserialization.

# Java ObjectInputStream

- Create an ObjectInputStream
- In order to create an object input stream, we must import the `java.io.ObjectInputStream` package first. Once we import the package, here is how we can create an input stream.
- `// Creates a file input stream linked with specified file`
- `FileInputStream fileStream = new FileInputStream(String file);`
- `// Creates an object input stream using the file input stream`
- `ObjectInputStream objStream = new ObjectInputStream(fileStream);`
- In the above example, we have created an object input stream named `objStream` that is linked with the file input stream named `fileStream`.
- Now, the `objStream` can be used to read objects from the file.

# Java ObjectOutputStream

- The ObjectOutputStream class of the java.io package can be used to write objects that can be read by ObjectInputStream.
- It extends the OutputStream abstract class.
- Working of ObjectOutputStream
- Basically, the ObjectOutputStream encodes Java objects using the class name and object values. And, hence generates corresponding streams. This process is known as serialization.
- Those converted streams can be stored in files and can be transferred among networks.
- Note: The ObjectOutputStream class only writes those objects that implement the Serializable interface. This is because objects need to be serialized while writing to the stream

# Java ObjectOutputStream

- Create an ObjectOutputStream
- In order to create an object output stream, we must import the `java.io.ObjectOutputStream` package first. Once we import the package, here is how we can create an output stream.
- `// Creates a FileOutputStream where objects from ObjectOutputStream are written`
- `FileOutputStream fileStream = new FileOutputStream(String file);`
- `// Creates the ObjectOutputStream`
- `ObjectOutputStream objStream = new ObjectOutputStream(fileStream);`
- In the above example, we have created an object output stream named `objStream` that is linked with the file output stream named `fileStream`.

# Serialization and Deserialization

- **Serialization in Java** is a mechanism of *writing the state of an object into a byte-stream*. It is mainly used in Hibernate, RMI (Remote Method Invocation), JPA (Java Persistence API), EJB (Enterprise JavaBeans) and JMS (Java Message Service) technologies.
- The reverse operation of serialization is called *deserialization* where byte-stream is converted into an object.
- The serialization and deserialization process is platform-independent, it means you can serialize an object on one platform and deserialize it on a different platform.

# Serialization and Deserialization

For serializing the object, we call the **writeObject()** method of *ObjectOutputStream* class, and for deserialization we call the **readObject()** method of *ObjectInputStream* class.

We must have to implement the *Serializable* interface for serializing the object.

## Advantages of Java Serialization

It is mainly used to travel object's state on the network (that is known as marshalling).

# Serialization and Deserialization

## **java.io.Serializable** interface

The **Serializable** interface must be implemented by the class whose object needs to be persisted.

The String class and all the wrapper classes implement the *java.io.Serializable* interface by default.

# Serialization and Deserialization

```
import java.io.Serializable;
public class Student implements Serializable{
    int id;
    String name;
    public Student(int id, String name) {
        this.id = id;
        this.name = name;
    }
}
```

In the above example, ***Student*** class implements Serializable interface. Now its objects can be converted into stream.

# Serialization and Deserialization

## ObjectOutputStream class

The ObjectOutputStream class is used to write primitive data types, and Java objects to an OutputStream.

Method	Description
1) public final void writeObject(Object obj) throws IOException {}	It writes the specified object to the ObjectOutputStream.
2) public void flush() throws IOException {}	It flushes the current output stream.
3) public void close() throws IOException {}	It closes the current output stream.

# Serialization and Deserialization

## ObjectInputStream class

An ObjectInputStream deserializes objects and primitive data written using an ObjectOutputStream.

Method	Description
1) <code>public final Object readObject() throws IOException, ClassNotFoundException {}</code>	It reads an object from the input stream.
2) <code>public void close() throws IOException {}</code>	It closes ObjectInputStream.

# Serialization and Deserialization

## ObjectInputStream class

An ObjectInputStream deserializes objects and primitive data written using an ObjectOutputStream.

Method	Description
1) <code>public final Object readObject() throws IOException, ClassNotFoundException {}</code>	It reads an object from the input stream.
2) <code>public void close() throws IOException {}</code>	It closes ObjectInputStream.

```
import java.io.*;
class Persist{
    public static void main(String args[]){
        try{
            //Creating the object
            Student s1 =new Student(211,"ravi");
            //Creating stream and writing the object
            FileOutputStream fout=new FileOutputStream("f.txt");
            ObjectOutputStream out=new ObjectOutputStream(fout);

            out.writeObject(s1);
            out.flush();
            //closing the stream
            out.close();
            System.out.println("success");
        }catch(Exception e){System.out.println(e);}
    }
}
```

```
import java.io.*;
class Depersist{
    public static void main(String args[]){
        try{
            //Creating stream to read the object
            ObjectInputStream in=new ObjectInputStream(new FileInputStream
            Stream("f.txt"));
            Student s=(Student)in.readObject();
            //printing the data of the serialized object
            System.out.println(s.id+" "+s.name);
            //closing the stream
            in.close();
        }catch(Exception e){System.out.println(e);}
    }
}
```

# Java Reader Class

- The Reader class of the java.io package is an abstract superclass that represents a stream of characters.
- Since Reader is an abstract class, it is not useful by itself. However, its subclasses can be used to read data.
- Subclasses of Reader
- In order to use the functionality of Reader, we can use its subclasses. Some of them are:

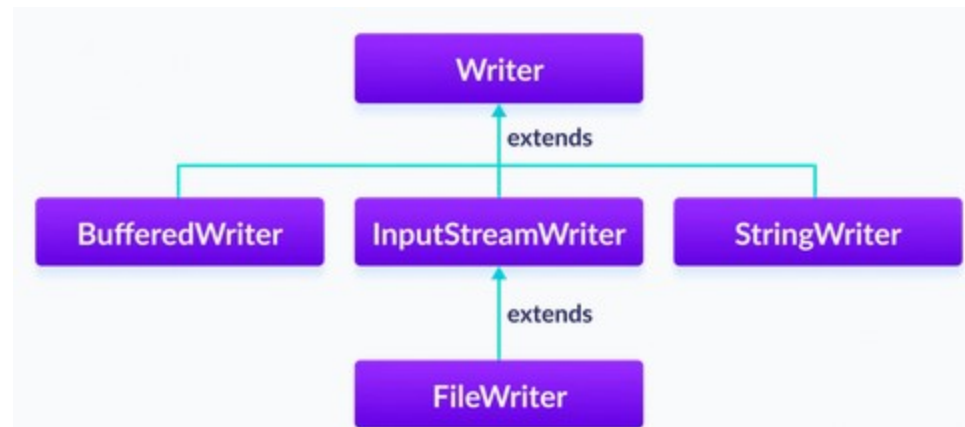

- BufferedReader
- InputStreamReader
- FileReader
- StringReader

# Java Writer Class

- The Writer class of the java.io package is an abstract superclass that represents a stream of characters.
- Since Writer is an abstract class, it is not useful by itself. However, its subclasses can be used to write data.
- Subclasses of Writer
- In order to use the functionality of the Writer, we can use its subclasses. Some of them are:

- BufferedWriter
- OutputStreamWriter
- FileWriter
- StringWriter

# Java InputStreamReader Class

- The InputStreamReader class of the java.io package can be used to convert data in bytes into data in characters.
- It extends the abstract class Reader.
- The InputStreamReader class works with other input streams. It is also known as a bridge between byte streams and character streams. This is because the InputStreamReader reads bytes from the input stream as characters.
- For example, some characters required 2 bytes to be stored in the storage. To read such data we can use the input stream reader that reads the 2 bytes together and converts into the corresponding character.

# Java InputStreamReader Class

- Create an InputStreamReader
- In order to create an InputStreamReader, we must import the `java.io.InputStreamReader` package first. Once we import the package here is how we can create the input stream reader.
- `// Creates an InputStream`
- `FileInputStream file = new FileInputStream(String path);`
- `// Creates an InputStreamReader`
- `InputStreamReader input = new InputStreamReader(file);`
- In the above example, we have created an InputStreamReader named input along with the FileInputStream named file.

# Java InputStreamReader Class

## Methods of InputStreamReader

The `InputStreamReader` class provides implementations for different methods present in the `Reader` class.

### **read() Method**

- `read()` - reads a single character from the reader
- `read(char[] array)` - reads the characters from the reader and stores in the specified array
- `read(char[] array, int start, int length)` - reads the number of characters equal to `length` from the reader and stores in the specified array starting from the `start`

# Java InputStr

- For example, suppose we have a file named input.txt with the following content.
- This is a line of text inside the file.

```
class Main {  
    public static void main(String[] args) {  
  
        // Creates an array of character  
        char[] array = new char[100];  
  
        try {  
            // Creates a FileInputStream  
            FileInputStream file = new FileInputStream("input.txt");  
  
            // Creates an InputStreamReader  
            InputStreamReader input = new InputStreamReader(file);  
  
            // Reads characters from the file  
            input.read(array);  
            System.out.println("Data in the stream:");  
            System.out.println(array);  
  
            // Closes the reader  
            input.close();  
        }  
  
        catch(Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# Java OutputStreamWriter Class

- The OutputStreamWriter class of the java.io package can be used to convert data in character form into data in bytes form.
- It extends the abstract class Writer.
- The OutputStreamWriter class works with other output streams. It is also known as a bridge between byte streams and character streams. This is because the OutputStreamWriter converts its characters into bytes.
- For example, some characters require 2 bytes to be stored in the storage. To write such data we can use the output stream writer that converts the character into corresponding bytes and stores the bytes together.

# Java OutputStreamWriter Class

- Create an OutputStreamWriter
- In order to create an OutputStreamWriter, we must import the `java.io.OutputStreamWriter` package first. Once we import the package here is how we can create the output stream writer.
- `// Creates an OutputStream`
- `FileOutputStream file = new FileOutputStream(String path);`
- `// Creates an OutputStreamWriter`
- `OutputStreamWriter output = new OutputStreamWriter(file);`
- In the above example, we have created an OutputStreamWriter named output along with the FileOutputStream named file.

# Java OutputStreamWriter Class

- **Methods of OutputStreamWriter**

## **write() Method**

- `write()` - writes a single character to the writer
- `write(char[] array)` - writes the characters from the specified array to the writer
- `write(String data)` - writes the specified string to the writer

# Java OutputStreamWriter Class

```
public class Main {  
  
    public static void main(String args[]) {  
  
        String data = "This is a line of text inside the file.";  
  
        try {  
            // Creates a FileOutputStream  
            FileOutputStream file = new FileOutputStream("output.txt");  
  
            // Creates an OutputStreamWriter  
            OutputStreamWriter output = new OutputStreamWriter(file);  
  
            // Writes string to the file  
            output.write(data);  
  
            // Closes the writer  
            output.close();  
        }  
  
        catch (Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# Java FileReader Class

- The FileReader class of the java.io package can be used to read data (in characters) from files.
- It extends the InputSreamReader class.
- Create a FileReader
- In order to create a file reader, we must import the java.io.FileReader package first. Once we import the package, here is how we can create the file reader.
- Using the name of the file
- `FileReader input = new FileReader(String name);`
- Here, we have created a file reader that will be linked to the file specified by the name

# Java FileReader Class

The `FileReader` class provides implementations for different methods present in the `Reader` class.

## **read() Method**

- `read()` - reads a single character from the reader
- `read(char[] array)` - reads the characters from the reader and stores in the specified array
- `read(char[] array, int start, int length)` - reads the number of characters equal to `length` from the reader and stores in the specified array starting from the position `start`

# Java FileReader Class

```
class Main {  
    public static void main(String[] args) {  
  
        // Creates an array of character  
        char[] array = new char[100];  
  
        try {  
            // Creates a reader using the FileReader  
            FileReader input = new FileReader("input.txt");  
  
            // Reads characters  
            input.read(array);  
            System.out.println("Data in the file: ");  
            System.out.println(array);  
  
            // Closes the reader  
            input.close();  
        }  
  
        catch(Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# Java FileWriter Class

- The FileWriter class of the java.io package can be used to write data (in characters) to files.
- It extends the OutputStreamWriter class.
- Create a FileWriter
- In order to create a file writer, we must import the Java.io.FileWriter package first. Once we import the package, here is how we can create the file writer.
- Using the name of the file
- `FileWriter output = new FileWriter(String name);`

# Java FileWriter Class

## **write() Method**

- `write()` - writes a single character to the writer
- `write(char[] array)` - writes the characters from the specified array to the writer
- `write(String data)` - writes the specified string to the writer

# Java FileWriter Class

```
public class Main {  
  
    public static void main(String args[]) {  
  
        String data = "This is the data in the output file";  
  
        try {  
            // Creates a FileWriter  
            FileWriter output = new FileWriter("output.txt");  
  
            // Writes the string to the file  
            output.write(data);  
  
            // Closes the writer  
            output.close();  
        }  
  
        catch (Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# Java BufferedReader

- The BufferedReader class of the java.io package can be used with other readers to read data (in characters) more efficiently.
- It extends the abstract class Reader.
- Working of BufferedReader
- The BufferedReader maintains an internal buffer of 8192 characters.
- During the read operation in BufferedReader, a chunk of characters is read from the disk and stored in the internal buffer. And from the internal buffer characters are read individually.
- Hence, the number of communication to the disk is reduced. This is why reading characters is faster using BufferedReader.

# Java BufferedReader

- Create a BufferedReader
- In order to create a BufferedReader, we must import the `java.io.BufferedReader` package first. Once we import the package, here is how we can create the reader.
- `// Creates a FileReader`
- `FileReader file = new FileReader(String file);`
- `// Creates a BufferedReader`
- `BufferedReader buffer = new BufferedReader(file);`
- In the above example, we have created a `BufferedReader` named `buffer` with the `FileReader` named `file`.

# Java BufferedReader

## Methods of BufferedReader

The `BufferedReader` class provides implementations for different methods present in `Reader`.

### **read() Method**

- `read()` - reads a single character from the internal buffer of the reader
- `read(char[] array)` - reads the characters from the reader and stores in the specified array
- `read(char[] array, int start, int length)` - reads the number of characters equal to `length` from the reader and stores in the specified array starting from the position `start`

# Java BufferedReader

```
class Main {  
    public static void main(String[] args) {  
  
        // Creates an array of character  
        char[] array = new char[100];  
  
        try {  
            // Creates a FileReader  
            FileReader file = new FileReader("input.txt");  
  
            // Creates a BufferedReader  
            BufferedReader input = new BufferedReader(file);  
  
            // Reads characters  
            input.read(array);  
            System.out.println("Data in the file: ");  
            System.out.println(array);  
  
            // Closes the reader  
            input.close();  
        }  
  
        catch(Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# Java BufferedWriter Class

- The BufferedWriter class of the java.io package can be used with other writers to write data (in characters) more efficiently.
- It extends the abstract class Writer.
- Working of BufferedWriter
- The BufferedWriter maintains an internal buffer of 8192 characters.
- During the write operation, the characters are written to the internal buffer instead of the disk. Once the buffer is filled or the writer is closed, the whole characters in the buffer are written to the disk.
- Hence, the number of communication to the disk is reduced. This is why writing characters is faster using BufferedWriter.

# Java BufferedWriter Class

- Create a BufferedWriter
- In order to create a BufferedWriter, we must import the `java.io.BufferedWriter` package first. Once we import the package here is how we can create the buffered writer.
- `// Creates a FileWriter`
- `FileWriter file = new FileWriter(String name);`
- `// Creates a BufferedWriter`
- `BufferedWriter buffer = new BufferedWriter(file);`
- In the above example, we have created a BufferedWriter named `buffer` with the FileWriter named `file`.

# Java BufferedWriter Class

## Methods of BufferedWriter

The `BufferedWriter` class provides implementations for different methods present in `Writer`.

### **write() Method**

- `write()` - writes a single character to the internal buffer of the writer
- `write(char[] array)` - writes the characters from the specified array to the writer
- `write(String data)` - writes the specified string to the writer

# Java BufferedWriter Class

```
public class Main {  
  
    public static void main(String args[]) {  
  
        String data = "This is the data in the output file";  
  
        try {  
            // Creates a FileWriter  
            FileWriter file = new FileWriter("output.txt");  
  
            // Creates a BufferedWriter  
            BufferedWriter output = new BufferedWriter(file);  
  
            // Writes the string to the file  
            output.write(data);  
  
            // Closes the writer  
            output.close();  
        }  
  
        catch (Exception e) {  
            e.printStackTrace();  
        }  
    }  
}
```

# StringTokenizer

The **java.util.StringTokenizer** class allows you to break a String into tokens. It is simple way to break a String.

In the StringTokenizer class, the delimiters can be provided at the time of creation or one by one to the tokens.

# StringTokenizer

**Hello Walking techie how are you**

**StringTokenizer**

```
graph TD; A[Hello Walking techie how are you] --> B[StringTokenizer]; B --> C[Tokens]; C --> D[Hello]; C --> E[Walking]; C --> F[techie]; C --> G[how]; C --> H[are]; C --> I[you];
```

**Tokens**

**Hello Walking techie how are you**

# StringTokenizer

Constructor		Description
StringTokenizer(String str)		It creates StringTokenizer with specified string.
StringTokenizer(String str,	String delim)	It creates StringTokenizer with specified string and delimiter.

Methods		Description
boolean hasMoreTokens()		It checks if there is more tokens available.
String nextToken()		It returns the next token from the StringTokenizer object.
String	nextToken(String delim)	It returns the next token based on the delimiter.

# StringTokenizer

```
import java.util.StringTokenizer;

public class Simple{
    public static void main(String args[]){
        StringTokenizer st = new StringTokenizer("my name is
vivek"," ");

        while (st.hasMoreTokens()) {
            System.out.println(st.nextToken());
        }
    }
}
```

# StringTokenizer

```
import java.util.*;

public class Test {
    public static void main(String[] args) {
        StringTokenizer st = new StringTokenizer("my,name,is,vivek");

        // printing next token
        System.out.println("Next token is : " + st.nextToken(","));
    }
}
```
